PRODUCT EVALUATED:
STEEL DOOR IN PAIRS WITH GLAZED APERTURES

EVALUATION PROPERTY: Air Leakage

Report of steel door in pairs with glazed apertures for the requirements of UL 1784, *Air Leakage Tests of Door Assemblies – July 10, 2009.*

1 Table of Contents

2 Introduction

Intertek Testing Services NA Ltd. (Intertek) has conducted physical testing on a door product for Samhoon Co. Ltd. The testing was carried out in accordance with UL 1784, *Air Leakage Tests of Door Assemblies – 10 July, 2009.* This evaluation was completed during the month of September 2014.

3 Test Samples

3.1. SAMPLE SELECTION

The door arrived at the Evaluation Center on September 24, 2014. Samples were not independently selected for testing.

3.2. SAMPLE AND ASSEMBLY DESCRIPTION

The product was identified as a steel door in pairs with glazed apertures.

Frame: Welded steel frame 1.6mm thick. Dimensions: 150mm depth, 45mm face, 50mm rebate, 16mm door stop, 50mm soffit, 19mm back bend and 112mm throat. Frame came pre-fitted to accept 114mm (~4 ½in.) butt hinges and also anchor bolts through welded bolt guides. Overall frame size: 2390 x 2200mm (w x h). Frame finish was supplied with a primer coat.

Door: Steel door made from 1.2mm thick sheet metal 42.5mm thick filled with insulation within the cavity. Overall size: 1148 x 2155mm (w x h).

Aperture: 6mm tempered glass vision panel with total visible light area of 150 x 800mm (w x h) mounted within and aperture with a metal beading 19.05 x 18.65mm (depth x h) 1.6mm thick with a 19.05mm metal flange for screw fixings. Overall size: 226 x 876mm (w x h).

Additional specimen details can be found in APPENDIX C – Drawings.

4 Testing and Evaluation Methods

4.1. CONDITIONING

Unless otherwise stated, the sample materials were maintained in standard laboratory conditions for a minimum of 24 hours at a temperature of 73 ± 4°F (23 ± 2°C) and relative humidity of 50 ± 5%.

4.2. CYCLING TEST

The cycling test was conducted as per section 6 of UL 1784. Upon completion of the cycling test the same sample was used for air leakage. The test chamber was fitted with a pressure tap to measure the chamber pressure. 9 thermocouples were installed spaced evenly within the test chamber to measure all parts of the test sample. The junction of the thermocouples were placed 6in away from the exposed face of the sample. The temperature and pressure were recorded at intervals not exceeding 5 minutes.

4.3. AIR LEAKAGE

Air leakage was conducted in accordance with Section 7 of UL 1784. The product was installed into a test chamber consisting of a sealed chamber with one open side in which the test sample is installed and sealed. A pressure tap was provided to measure the chamber pressure. An artificial seal was applied to the ungasketed bottom gap of the test sample.

The clearances between the door and the frame were measured at three points along each horizontal and vertical edge. Clearances are outlined in Table 1 below.

Table 1. Clearances Between Door and Frame

Location	Clearances (mm)			Average (mm)
Vertical – Left	1.5	1.6	1.5	**1.566**
Horizontal – Top	**2.66** (avg. of 3)	**2.56** (avg. of 3)	-	**2.61**
Vertical – Right	1.5	1.6	1.6	**1.566**

The test was performed using pressure differentials of 0.05 in. H2O (12.5 Pa), 0.10 in. H2O (25 Pa), 0.20 in. H2O (50 Pa), and 0.30 in. H2O (75 Pa) for both infiltration and exfiltration at ambient and elevated temperatures.

Extraneous chamber leakage rate at ambient was performed first by using a polyethylene sheet to cover the test specimen only. The air flow was then adjusted to the above mentioned pressure differentials. After conditions stabilized, the air flow through the metering system and test pressure difference was measured and recorded. The sheet was then removed and the overall leakage rate was measured and recorded at the specified pressure differentials. The temperature within the test chamber was then adjusted to achieve a temperature of 400 ± 10°F (204 ± 5°C) within 30 minutes. With the temperature stabilized, the overall leakage rate at elevated temperature was measured and recorded at the specified pressure differentials. The system was then allowed to cool and once the specimen surface temperature had returned to within 20°F, the polyethylene sheet was re-applied, and the extraneous chamber leakage was measured and recorded again. Specimen leakage can be calculated as the difference between the overall system leakage and extraneous chamber leakage.

5 Testing and Evaluation Results

The test results for the Samhoon Co. Ltd. door product are shown in Table 2 below. A copy of the data sheets can be found in the Appendices.

Table 2. Samhoon Co. Ltd.

Description	Temperature (°C)	Pressure Differential (Pa)	Away from the seal		Towards the seal	
			(CFM)	CFM/ft²	(CFM)	CFM/ft²
STEEL DOOR IN PAIRS WITH GLAZED APERTURES	23	12.5	7.56	0.13	4.81	0.09
		25	8.25	0.15	6.18	0.11
		50	9.62	0.17	8.25	0.15
		75	10.31	0.18	6.87	0.12
	204	12.5	2.75	0.05	5.50	0.10
		25	6.18	0.11	10.31	*0.18
		50	4.12	0.07	4.12	0.07
		75	6.18	0.11	6.18	0.11

*The maximum air leakage measured at 0.1 in. H2O was 0.18 CFM/ft² at elevated temperatures when the sample was tested with the chamber pressure pushing the door away towards the seals.

6 Conclusion

The Samhoon Co. Ltd. door product identified and evaluated in this report has been tested in accordance with UL 1784, *Air Leakage Tests of Door Assemblies – 10 July, 2009.* The product test results are presented in Section 5 of this report.
